Introduction to Satellite Navigation and Positioning

Homework 3

November 11, 2011

Josh Wildey

Josh Wildey
Homework 3
11/11/2011

Objective:

The first task at hand is to compute the ionosphere-free measurement calculations of the pseudorange and pseudorange rate using dual frequency measurement techniques. It is then required to estimate the frequency and clock biases using the given data. Then, from these measurements and calculations, determine the stability of the oscillator and use the carrier phase to smooth out the pseudorange measurement. The next task is to implement the Klobuchar model to estimate the lonosphere delay and to calculate the corrected model and compare this model to the pseudorange measurements. Lastly, given another set of data, the tropospheric delay needs to be calculated by implementing the Sasstamoinen and Hopfield Models. These models are then to be used for comparing the mapping function between flat-earth, Misra and Enge, and Chao Mapping function coefficients.

Given Data:

files: rawdata.sv13, orbit.sv13, dualfreq.sv1, DH010600.MET

ECEF Location of CORS Station:

X = -1288337.0539 m

Y = -4721990.4483 m

 $Z = 4078321.6617 \, m$

$lpha_{\scriptscriptstyle 0}$	α_1	α_2	α_3
0.028×10^{-6}	-0.007 x 10 ⁻⁶	-0.119 x 10 ⁻⁶	0.199 x 10 ⁻⁶
$\boldsymbol{\mathcal{G}}_{o}$	$oldsymbol{eta_1}$	$oldsymbol{eta_2}$	$\boldsymbol{\mathcal{6}_{3}}$
137.0 x 10 ³	-49.0×10^3	-131.0 x 10 ³	-262.0 x 10 ³

ECEF Location of Durmid Hill GPS Station:

 $\Phi = 33.390^{\circ} N$

 $\lambda = 115.79^{\circ} W$

h = 0 m

11/11/2011

Problem 1:

Part 1:

To calculate the ionosphere free pseudoranges the following equations were used:

$$\rho_{L1} = \rho^* + \frac{A}{f_{L1}^2}$$

$$\rho_{L2} = \rho^* + \frac{A}{f_{L2}^2}$$

Solving for A leads to a value of:

$$A = \frac{f_{L1}^2 f_{L2}^2}{f_{L1}^2 - f_{L2}^2} (\rho_{L2} - \rho_{L1})$$

Plugging this back into one of the equations and solving to the pseudorange, ρ^* , yields:

$$\rho^* = \frac{f_{L1}^2}{f_{L1}^2 - f_{L2}^2} \rho_{L1} - \frac{f_{L2}^2}{f_{L1}^2 - f_{L2}^2} \rho_{L2}$$

Similarly for the ionosphere free carrier phase scaled to the L1 frequency yields:

$$\varphi^* = \frac{f_{L1}^2}{f_{L1}^2 - f_{L2}^2} \varphi_{L1} - \frac{f_{L1}f_{L2}}{f_{L1}^2 - f_{L2}^2} \varphi_{L2}$$

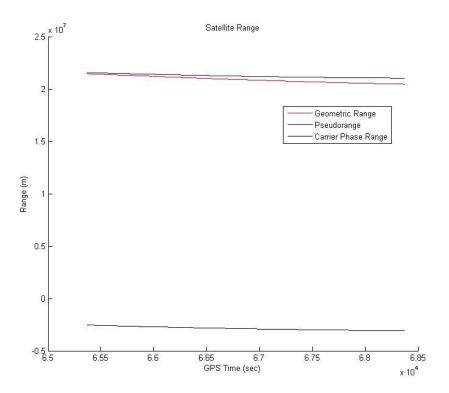

Figure 1- 1 Satellite Range

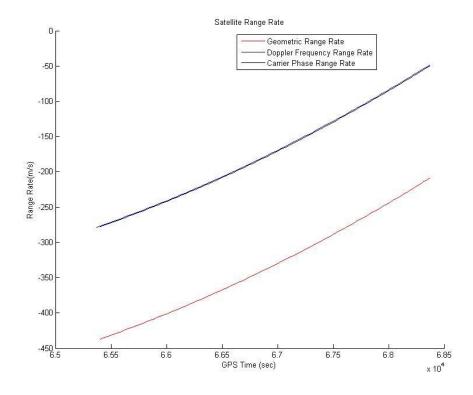

Figure 1-2 Satellite Range Rate

Part 2:

To determine the oscillator frequency bias, the following equation was used:

$$f_{b,S} = -f_D - \frac{\dot{r}}{\lambda}$$

To calculate the Line of Sight velocity the Frequency bias was multiplied by the wavelength of the frequency. Results can be seen in figures 1-3 and 1-4.

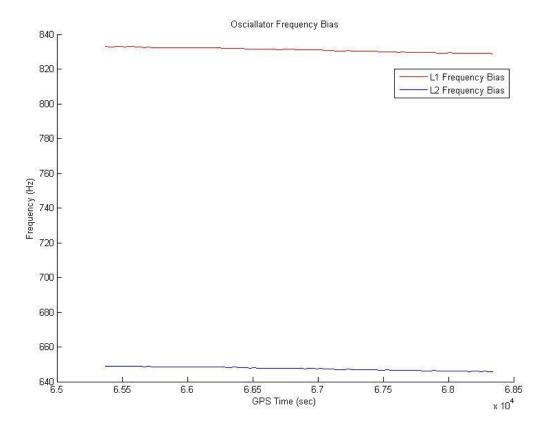

Figure 1-3 Oscillator Frequency Bias

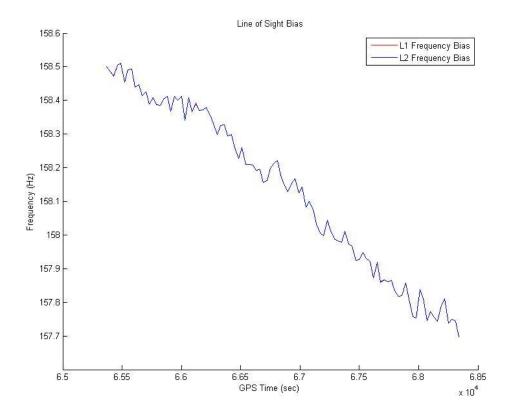

Figure 1-4 Line of Sight Bias

Problem 2 and 3:

To implement the Klobuchar model the following equations were used and were referenced from the IS-GPS-200E manual.

The ionospheric correction model is given by

$$T_{iono} = \begin{cases} F * \left[5.0 * 10^{-9} + (AMP) \left(1 - \frac{x^2}{2} + \frac{x^4}{24} \right) \right], |x| < 1.57 \\ F * \left(5.0 * 10^{-9} \right) \end{cases}$$
 (sec)

where

 T_{iono} is referred to the L1 frequency; if the user is operating on the L2 frequency, the correction term must be multiplied by γ (reference paragraph 20.3.3.3.3.2),

$$AMP = \begin{cases} \sum_{n=0}^{3} \alpha_n \varphi_m^n, \ AMP \geq 0 \\ \text{if } AMP < 0, \ AMP = 0 \end{cases} \quad (\text{sec})$$

$$x = \frac{2\pi (t - 50400)}{PER}$$
 (radians)

$$PER = \begin{cases} \sum_{n=0}^{3} \beta_{n} \phi_{m}^{n}, & PER \ge 72,000 \\ if & PER < 72,000, & PER = 72,000 \end{cases}$$
 (sec)

$$F = 1.0 + 16.0 [0.53 - E]^3$$

and α_n and β_n are the satellite transmitted data words with n = 0, 1, 2, and 3.

Figure 20-4. Ionospheric Model (Sheet 1 of 3)

Other equations that must be solved are

$$\phi_m = \phi_i + 0.064\cos(\lambda_i - 1.617)$$
 (semi-circles)

$$\lambda_i = \lambda_u + \frac{\psi \sin A}{\cos \phi_i}$$
 (semi-circles)

$$\begin{split} \varphi_i = \left\{ \begin{array}{ccc} & \varphi_u + \psi \; cos A, & \left| \varphi_i \right| \leq 0.416 \\ & if \; \varphi_i > +0.416, \; then \; \; \varphi_i = +0.416 \\ & if \; \varphi_i < -0.416, \; then \; \; \varphi_i = -0.416 \end{array} \right\} \end{aligned} \tag{semi-circles}$$

$$\psi = \frac{0.0137}{E + 0.11} - 0.022$$
 (semi-circles)

$$t = 4.32 (10^4) \lambda_i + GPS time$$
 (sec)

where

 $0 \le t < 86400$: therefore, if $t \ge 86400$ seconds, subtract 86400 seconds;

if t < 0 seconds, add 86400 seconds.

Figure 20-4. Ionospheric Model (Sheet 2 of 3)

The following figure show the results.

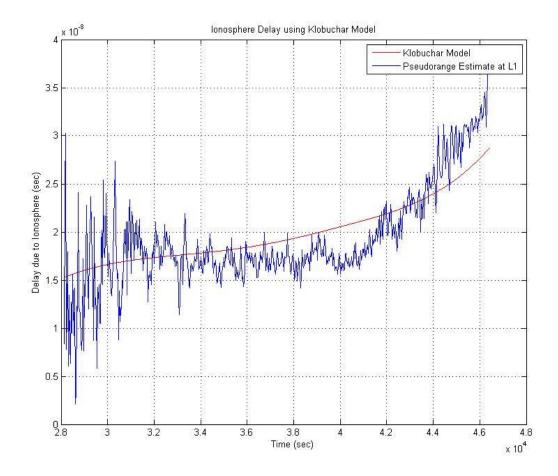

Figure 1- -5 Klobuchar Model and Pseudorange estimation

The pseudorange was estimated using the following equations:

$$A = \frac{f_{L1}^2 f_{L2}^2}{f_{L1}^2 - f_{L2}^2} (\rho_{L1} - \rho_{L2})$$

$$\tau_{lonosphere\ Delay} = \frac{A}{c f_{L1}^2}$$

$$\tau_{Ionosphere\ Delay} = \frac{A}{cf_{L1}^2}$$

Although the pseudorange estimation is very noisy, the Klobuchar model can still be seen to model the pseudorange with the same general curvature. It is not perfect, but represents a decent model.

Problem 4:

To implement the Sasstamoinen model the following equations were used:

$$e_0 = 6.108 * RH * exp\left(\frac{17.15T - 4684}{T - 38.5}\right)$$

$$c\tau_{T,Z,Dry} = .0022777(1 + .0026\cos 2\phi + .0008H)P_0$$

$$c\tau_{T,Z,Wet} = .0022777\left(\frac{1255}{T_0} + .05\right)e_0$$

To implement the Hopfield Model the following equations were used:

$$h_d = 40136 + 148.72(T - 273.16)$$

$$h_w = 11000$$

$$c\tau_{T,Z,Dry} = 77.64 \times 10^{-6} \left(\frac{P_0 h_d}{5T}\right)$$

$$c\tau_{T,Z,Wet} = 0.373 \left(\frac{e_0 h_w}{5T^2}\right)$$

The results are as follows:

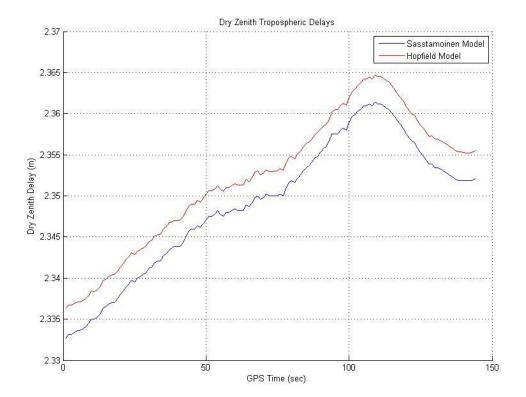

Figure 1-Error! No text of specified style in document.6 Dry Zenith Delays

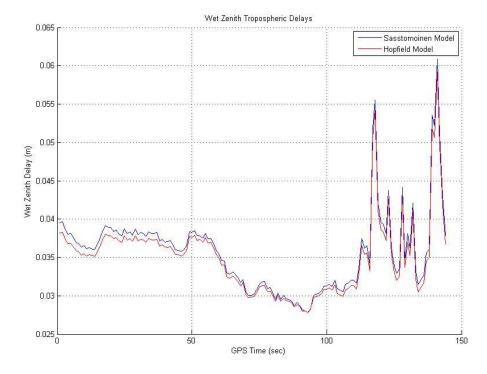

Figure 1-7 Wet Zenith Delays

Both models of tropospheric delays are very similar with only minor offsets in their values and could be used interchangeably for correct results.

Problem 5:

To compare the three different mapping functions the following coefficients and equations were used:

For simple flat-earth Mapping:

$$m(EL) = \frac{1}{\sin(EL)}$$

For Misra and Enge Mapping:

$$m(EL) = \frac{1}{\sqrt{1 - \left(\frac{\cos(EL)}{1.001}\right)^2}}$$

For Chao Mapping:

$$m_{Dry}(EL) = \frac{1}{\sin(EL) + \frac{0.00143}{\tan(EL) + 0.0445}}$$

$$m_{Wet}(EL) = \frac{1}{\sin(EL) + \frac{0.00035}{\tan(EL) + 0.017}}$$

The total tropospheric delay can be represented by the following equation:

$$\tau_{Total\ Tropospheric\ Delay} = \tau_{T,Z,Wet} m_{Wet}(EL) + \tau_{T,Z,Dry} m_{Dry}(EL)$$

The total tropospheric delay was calculated for elevation angles of 5°, 15°, 45°, and 85° and can be seen in the following figures.

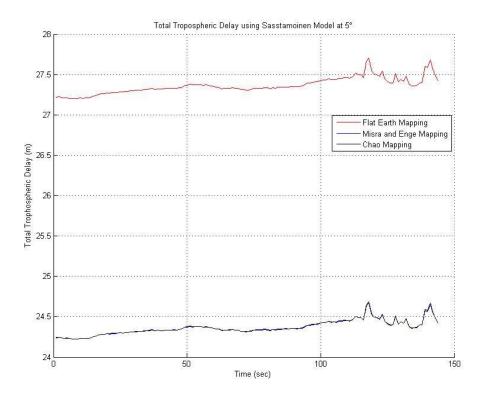

Figure 1-8

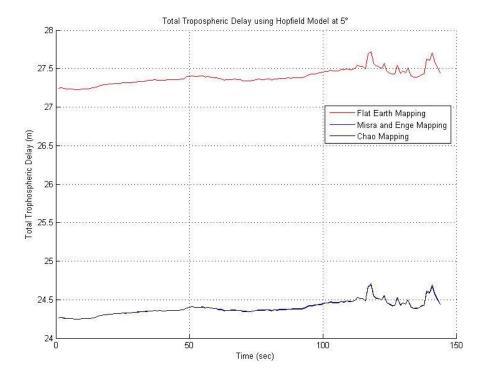

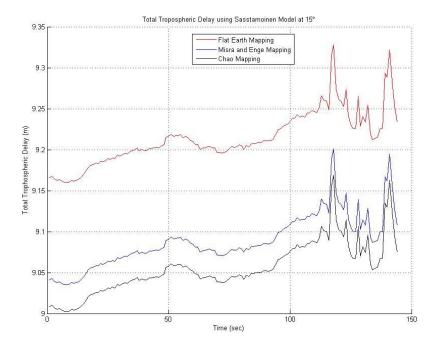

Figure 1-9

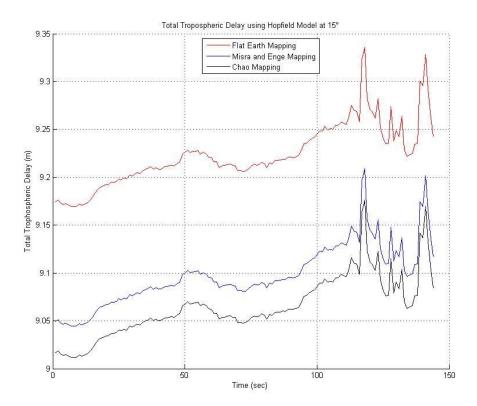

Figure 1-10

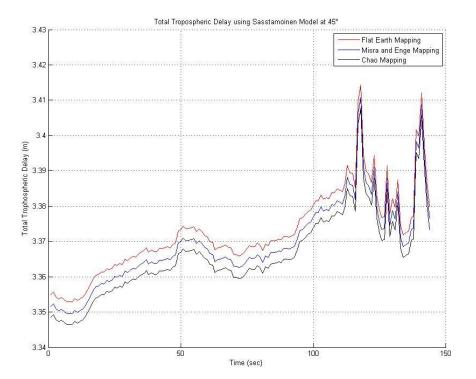

Figure 1-11

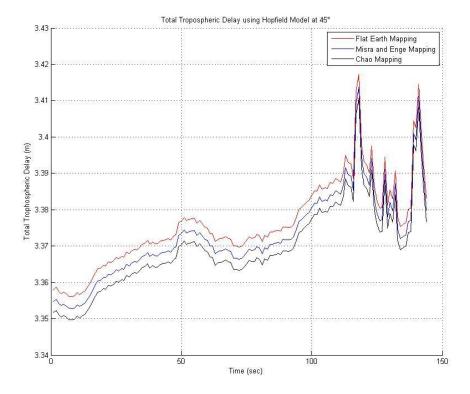

Figure 1-12

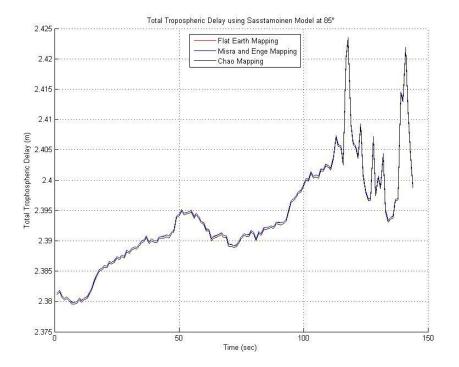

Figure 1-13

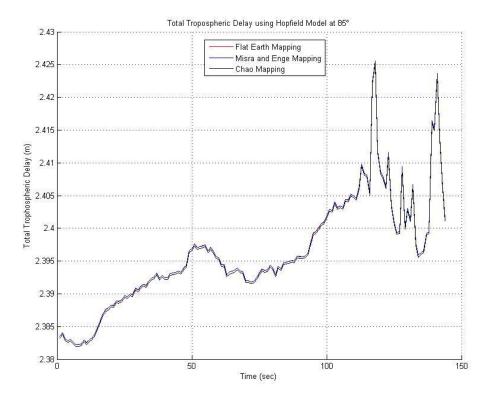

Figure 1-14

As shown in these figures, as the elevation angle gets closer and closer to 90° the different models become almost identical. At low elevation angles there are high error rates, especially with the flat earth mapping function as it is known to produce bad results below 15°. It is also observed that the actual delay decreases significantly as the elevation angle increases, again becoming more accurate and precise as the elevation angle increases. In the range between 5° and 85°, it is seen that the models still hold very similar shape and are just offset from each other.
